1 General

Most of GNAT is written in Ada using a consistent style to ensure readability of the code. This document has been written to help maintain this consistent style, while having a large group of developers work on the compiler.

For the coding style in the C parts of the compiler and run time, see the GNU Coding Guidelines.

This document is structured after the Ada Reference Manual. Those familiar with that document should be able to quickly lookup style rules for particular constructs.

3 Declarations and Types

- * In entity declarations, colons must be surrounded by spaces. Colons should be aligned.

```
Entity1    : Integer;
My_Entity : Integer;
```

- * Declarations should be grouped in a logical order. Related groups of declarations may be preceded by a header comment.
- * All local subprograms in a subprogram or package body should be declared before the first local subprogram body.
- * Do not declare local entities that hide global entities.
- * Do not declare multiple variables in one declaration that spans lines. Start a new declaration on each line, instead.
- * The defining_identifiers of global declarations serve as comments of a sort. So don't choose terse names, but look for names that give useful information instead.
- * Local names can be shorter, because they are used only within one context, where comments explain their purpose.
- * When starting an initialization or default expression on the line that follows the declaration line, use 2 characters for indentation.

```
Entity1 : Integer :=
    Function_Name (Parameters, For_Call);
```

- * If an initialization or default expression needs to be continued on subsequent lines, the continuations should be indented from the start of the expression.

```
Entity1 : Integer := Long_Function_Name
    (parameters for call);
```

4 Expressions and Names

- * Every operator must be surrounded by spaces. An exception is that this rule does not apply to the exponentiation operator, for which there are no specific layout rules. The reason for this exception is that sometimes it makes clearer reading to leave out the spaces around exponentiation.

$E := A * B^{**2} + 3 * (C - D);$

- * Use parentheses where they clarify the intended association of operands with operators:

$(A / B) * C$

```
while long_condition_that_has_to_be_split
  and then continued_on_the_next_line
loop
  ...
end loop;
```

If the loop_statement has an identifier, it is laid out as follows:

```
Outer : while not condition loop
  ...
end Outer;
```

5.5 Block Statements

- * The `declare` (optional), `begin` and `end` words are aligned, except when the block_statement is named. There is a blank line before the `begin` keyword:

```
Some_Block : declare
  ...

begin
  ...
end Some_Block;
```

```

        procedure Nested is
        begin
            ...
        end Nested;

-- Start of processing for Style1

begin
    ...
end Style1;

procedure Style2 is
    Var_Referenced_In_Nested : Integer;

    proc Nested;
    -- Comments ...

    -----
    -- Nested --
    -----

    procedure Nested is
    begin
        ...
    end Nested;

    -- Local variables

    Var_Referenced_Only_In_Style2 : Integer;

-- Start of processing for Style2

begin
    ...
end Style2;

```

For new code, we generally prefer Style2, but we do not insist on modifying all legacy occurrences of Style1, which is still much more common in the sources.

7 Packages and Visibility Rules

- * All program units and subprograms have their name at the end:

```
package P is
    ...
end P;
```

- * We will use the style of `use` -ing `with` -ed packages, with the context clauses looking like:

```
with A; use A;
with B; use B;
```

- * Names declared in the visible part of packages should be unique, to prevent name clashes when the packages are `use d`.

```
package Entity is
    type Entity_Kind is ...;
    ...
end Entity;
```

- * After the file header comment, the context clause and unit specification should be the first thing in a `program_unit`.

- * `Preelaborate`, `Pure` and `Elaborate_Body` pragmas should be added right after the package name, indented an extra level and using the parameterless form:

```
package Preelaborate_Package is
    pragma Preelaborate;
    ...
end Preelaborate_Package;
```
